

**1. You've created a web site and the registration page has some required fields. Would it be OK to just use the HTML5 required attribute? Explain.**

No, we need to also use client-side/server-side scripting. This is because not all browsers support HTML5 features and we can't assume that they will anytime soon.

**2. What is the difference between a get and post action for a form?**

get is the default value; the value of get causes the form data to be appended to the URL and sent to the web server

post is a more private method that transmits the form data in the body of the HTTP response (preferred by W3C)

**3. What is a query string? (google)**

A query string is a set of characters input to computer or Web browser and sent to a query program to recover specific information from a database.

On the Internet, a query string is part of the set of characters automatically input in the address bar of dynamic web site when a user makes a request for information according to certain criteria.

**4. What's the difference between hard and soft wrap in a textarea? (google)**

The text in a text area with wrap="hard" will contain newlines (if any) when submitted in a form.

The text in a text area with wrap="soft" is not wrapped when submitted in a form (default).
